

This is a text file that contains `daser1998@gmail.com` several email addresses `davixr2.0amazon@gmail.com` like the previous ones. From this text `davixrgithub@gmail.com` we expect Python to extract all the addresses and save them in a simple and easy to access set, which does not contain repeated emails `daser1998@gmail.com` and we need to check the end of `bydavixr@gmail.com`. Furthermore, it can detect multiple domain extensions like `tracasytracas@hotmail.com` or `thebestlvper@yahoo.com`. However, we need to create a `user@alumnos.uc3m.es` a searcher that gets an email list independently of the domain, since emails like `user@mit.edu` is not detected.
